Abstract

Feedback utterances are among the most frequent in dialogue. Feedback is also a crucial aspect of linguistic theories that take social interaction, involving language, into account. This paper introduces the corpora and datasets of a project scrutinizing this kind of feedback utterances in French. We present the genesis of the corpora (for a total of about 16 hours of transcribed and phone force-aligned speech) involved in the project. We introduce the resulting datasets and discuss how they are being used in on-going work with focus on the form-function relationship of conversational feedback. All the corpora created and the datasets produced in the framework of this project will be made available for research purposes.

1 Introduction

Feedback utterances are the most frequent utterance type in dialogue (Stolcke et al., 2000; Misu et al., 2011). They also play a crucial role in managing the common ground of a conversation (Clark, 1996). However, perhaps due to their apparent simplicity, they have been ignored in many linguistic studies on dialogue. The main contribution to the understanding of the feedback utterance type comes from neighboring fields: (i) Conversational Analysis (CA) has shed light on turn-taking including a careful description of response tokens, such as “uh-huh” (Schegloff, 1982), formerly also termed back-channels by (ii) computational linguist Victor Yngve (Yngve, 1970); (iii) Dialogue engineers dealt with them because of their ubiquity in task-oriented dialogues (Traum, 1994); (iv) Cognitive psychologists gave them an important role in their theory of communication (Clark, 1996); (v) The most linguistic attempt to describe feedback is the work by Allwood et al. (1992) who suggest a semantic framework for it.

We take the apparent lack of sophistication of the lexical forms and structures involved in the majority of feedback utterances to be an interesting feature for a multimodal study. In our opinion, multimodal corpus studies are suffering form a combinatorial explosion that results from the simultaneous integration of complex phenomena and structures from all levels of analysis. Our aim is to use feedback as a filtering constraint on large multimodal corpora. In this way, all the dimensions will be analyzed but in a restricted way: on feedback utterances. Feedback production is known to be dependent on the discourse situation. Therefore, a second aim is to provide a model that is not domain-restricted: our objective is rather a model that is generalisable enough to be interesting from a linguistic viewpoint.

These parameters lead us to constitute a dataset that is built from four different corpora recorded in four different situations: almost free conversation (CID corpus), Map Task (MTR corpus), Face-to-Face Map Task (MTX corpus), and discussion / negotiation centered on DVD movies (DVD corpus). Since the overall goal of the project is a study of the form-function relationship of feedback utterances, the corpora are needed to create rich datasets that include extracted features from the audio, video, and their transcriptions, as well as annotated functions of the feedback utterances.

In this paper, after coming back to definitions, terminology and related work (Section 2), we present how the corpora were created (Section 3), including various stages of non-trivial post-processing, how they were pre-segmented in the gestural domain and annotated for communicative functions. We also present the different datasets (Section 4), including automatically enriched tran-
scriptions and large feature files, how they were produced and how they can also be useful for other researchers and their studies.

2 Feedback items

Concerning the definition of the term feedback utterance, we follow Bunt (1994, p.27):

“Feedback is the phenomenon that a dialogue participant provides information about his processing of the partner’s previous utterances. This includes information about perceptual processing (hearing, reading), about interpretation (direct or indirect), about evaluation (agreement, disbelief, surprise,...) and about dispatch (fulfillment of a request, carrying out a command,...).”

As a working definition of our class feedback, we could have followed Gravano et al. (2012), who selected their tokens according to the individual word transcriptions. Alternatively, Neiberg et al. (2013) performed an acoustic automatic detection of potential feedback turns, followed by a manual check and selection. Given our objective, we preferred to use perhaps more complex units that are closer to feedback utterances. We consider that the feedback function is expressed overwhelmingly through short utterances or fragments (Ginzburg, 2012) or in the beginning of potentially longer contributions. We therefore automatically extracted candidate feedback utterances of these two kinds. Utterances are however already sophisticated objects that would require a specific segmentation campaign. We rely on a rougher unit: the Inter-Pausal Unit (IPU). IPUs are stretches of talk situated between silent pauses of a given duration, here 200 milliseconds. In addition to these isolated feedback IPUs, we added sequences of feedback-related lexical items situated at the very beginning of an IPU.

3 Corpora

Our collection is composed of four different corpora: an 8 hour conversational data corpus (Bertrand et al., 2008), a 2.5 hours MapTask corpus (Bard et al., 2013), a 2.5 hours face-to-face MapTask corpus (Gorisch et al., 2014) and a 4 hours DVD negotiation corpus. All these corpora are accessible as a collection of resources through the Ortolang platform (http://sldr.org/ortolang-

3.1 Corpus creation: Protocols, Recordings and Transcriptions

All recordings include headset microphone channels that were transcribed on IPU level and automatically aligned on word and phone level. The recording setups are illustrated in Figure 1. The first two corpora (CID and MTR) already existed before our current project, while the other two (MTX and DVD) were specifically recorded and transcribed (using SPPAS (Bigi, 2012)) for this project and are therefore explained in more detail below. CID, MTX and DVD primary are directly accessible for research purposes; MTR requires agreement from its creators.

![Figure 1: Recording setups of corpora.](image-url)

**CID** Conversation Interaction Data (CID) includes participants having a chat about “strange things” (Bertrand et al., 2008). Each interaction took 60 minutes. Three of them were additionally recorded on video. Figure 1a illustrates the setup.

**MTR** The remote condition of the French MapTask corpus (MTR) (Bard et al., 2013) follows the original MapTask protocol (Anderson et al., 1991), where the role of map giver and follower change through the 8 maps per session. An example of a pair of maps is illustrated in Figure 1b. In this condition, the participants could not see each other and were therefore not recorded on video.

**MTX** The face-to-face condition of the French MapTask corpus (MTX) (Gorisch et al., 2014) includes additional video recordings for both partic-
ipants individually as they could see each other
during the dialogue (cf. Figure 1c). Similar to
the remote condition, 4 maps were “given” by one
participant and “followed” by the other and vice
versa. Each map took ca. 5 minutes to complete.

DVD We recruited 16 participants to take part in
the recording of this corpus. The aim was to in-
volve them in a discussion on movies, DVDs, ac-
tors, and all other topics that they may come up
with during a 30 minute conversation. A set of
DVD boxes (with content) were placed on a table
in front of them: 4 on each side (see Figure 1d).
The instructions included that each participant can
take 2 of the 8 boxes home if they are on their side
once the recording session is finished (as compen-
sation for participation). Several weeks prior to
the recording session, the participants were asked
to fill out a short questionnaire answering four
questions: what are your preferred movie genres,
what are your three most preferred movies, what
are your dispreferred movie genres, and what are
your three most dispreferred movies. According
to the answers, we paired mis-matching partici-
pants, chose 8 DVDs and placed them on the two
sides in a way that maximises negotiation (who
takes which DVDs home). 2 dispreferred movies
or genres were placed on the own side and two
preferred ones were placed on the other side.

3.2 Post-processing
Due to clocking differences in the audio and video
recording devices and random image loss in the
video, both signals ran out of synchronisation over
time. For multimodal analyses, such desynchroni-
sation is not acceptable. The videos of the CID
corpus have been corrected by hand in order to
match the audio channels. A more precise and less
time-consuming procedure was developed for the
newer recordings of MTX and DVD, as it is de-
scribed by Gorisch and Prévot (2015). First, the
audio and video files were cut in a rough man-
ner to the approximate start time of the task, e.g.
maps in the MapTask. Second, a dynamic pro-
gramming approach took the audio channel of the
camera and aligned it to the headset microphone
mix in order to estimate the missing images for
each video. Third, scripts were used to extract
all images, insert images at the appropriate places
and recombine the images to a film that can run
synchronously with the headset microphone chan-
nels. This procedure helped to repair the videos of
2h (out of 2.5h) of the MTX corpus and the entire
DVD corpus.

3.3 Gesture pre-segmentation
As our project aims to describe conversational
feedback in general, the visible part of that feed-
back should receive sufficient attention, too. Three
of the four corpora include participants’ visibil-
ity and video recordings. An entire labelling of
all gestures of the corpus is however impossible.
Therefore, we employed two students (working
on gesture for their research) to perform a pre-
segmentation task. Those sections of a video that
involve feedback in the domain of gestures or fa-
cial expressions were segmented using the ELAN
tool in its segmentation mode (Wittenburg et al.,
2006). The focus on this pass was on recall rather
than precision since all the marked units will be
annotated later on for precise gestures and poten-
tially discarded if it turns out that they are not feed-
back.

3.4 Quantitative presentation
The content of all corpora that are included in
our SIP of CoFee database, sums up to almost 17
hours of actual speech duration, with a number of
268,581 tokens in 33,378 utterances (See Ta-
ble 1). This relatively large collection is used in
subsequent analyses in order to quantify the form-
function relationship of conversational feedback.
In Table 1, the column # Feedback includes all
(13,036) candidate feedback units (isolated IPUs
and initial of an IPU). How they have been se-
lected is explained in Section 4. The column #
Gestures indicates the number of pre-segmented
feedback gestures. In parenthesis is the number of
those gestures that co-occur with verbal feedback
items. The number of gestures however should not
be taken as indicator of importance of gestures in
different corpora: the CID corpus has only three
hours out of eight that include video-recording,
while MTX misses some video files due to tech-
nical issues (see Section 3.2).

4 Datasets
This section describes how the verbal units of
feedback have been selected from the transcrip-
tions, what basic features have been extracted and
what communicative functions have been (and are
currently) annotated in order to form the dataset
for the form-function analysis.
Extracting units of analysis. We first identified the small set of most frequent items composing feedback utterances by building the token distribution for Inter-Pausal Units (IPUs) of length 3 or less. The 10 most frequent forms are: oui / yeah (2781), mh (2321), d’accord / agree-right (1082), laughter (920), oui / yes (888), euh / uh (669), ok (632), ah (433), voilà / that’s it-right (360). The next ones are et / and (360), non / no (319), tu / you (287), alors / then (151), bon / well (150) and then follows a series of other pronouns and determiners with frequency dropping quickly. After qualitative evaluation, we excluded tu, et and alors as they were unrelated to feedback in these short isolated IPUs. Table 2 shows the feedback tokens and the number of occurrences in each corpus. In order to count multiple sayings of a token in an IPU, such as “oui oui”, they appear in separate rows indicated by a plus sign (+). The category complex simply corresponds to any other transcription in the IPUs; it includes mainly various feedback item combinations (ah oui d’accord, euh ben oui) and repeated material from the left context. This yielded us a dataset of 13,036 utterances.

Feature extraction and function annotation. In order to deepen our understanding of these feedback items, we extracted a set of form-related and contextual features. Concerning the form, aside the simplified transcription presented in Table 2, we included some features trying to describe the complex category (namely the presence of a given discourse marker in the unit or a repetition of the left context). Various acoustic features including duration, pitch, intensity and voice quality parameters were also extracted. Concerning contextual features, we extracted timing features within the speech environment (that provide us information about feedback timing and overlap), discourse lexical (initial and final n-grams) and acoustic (pitch, intensity, etc.) features defined in terms of properties of the previous IPU from speaker and interlocutor.

We currently run campaigns to annotate the remaining data with feedback communicative functions (acknowledgment, approval, answer, etc.). Completely annotated subdatasets are used to run form-function classification experiments and correlation testing (Prévote and Gorisch, 2014).

5 Conclusion

The SIP of CoFee is ready for consumption. It is a composition of corpora of varying recording situations, including multimodality, and datasets that can be – and are currently – used for the study of one of the most basic practices in human communication, namely feedback.
